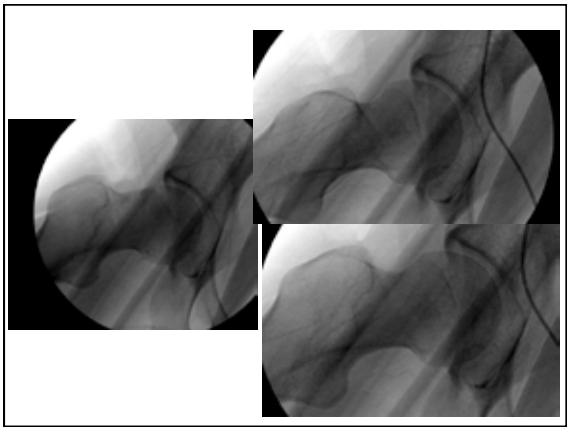
Indications for Open Management of FAI

Michael D. Stover, MD
Professor, Feinberg School of Medicine
Northwestern University

Principles of FAI Treatment

- Identify morphologic abnormalities, variants
- Understand how each impacts clinical presentation and joint damage
- Correction of pathomorphology
- Repair labral damage, adequately address cartilage damage

*Indications for surgery the same, techniques different



Pathologies most commonly reserved for open management

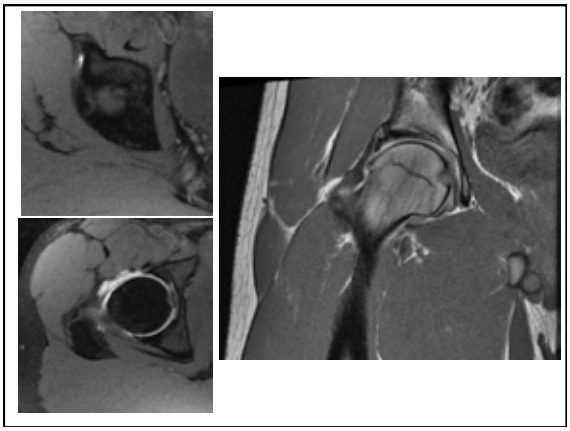
- Pathoanatomy not easily accessible by arthroscopic tools
  - Posterolateral extension of the cam deformity
  - Global acetabular overcoverage
    - Complete Labral reconstruction
- When reconstruction (not only resection) is needed
  - Usually with acquired deformities
    - SCFE
    - Perthes
- Address chondral defects (esp femur)
- Extra – articular impingement (specifically trochanteric)
- Very young patients
- Failed arthroscopic surgery

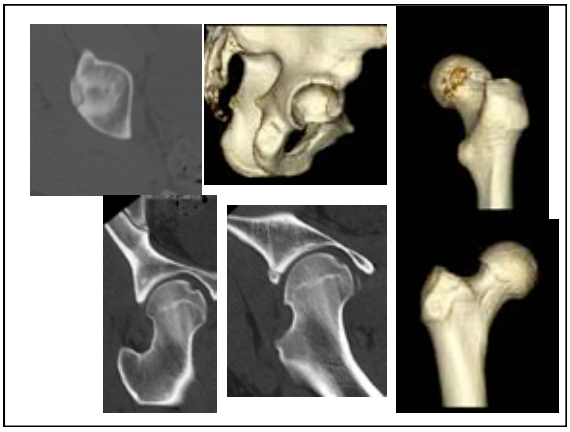
Impingement

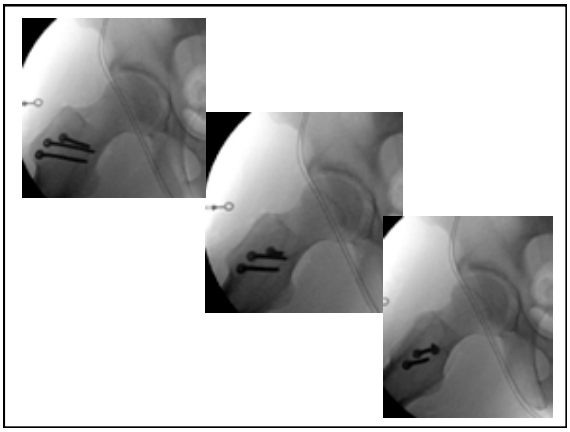
- Dynamic process
  - Open surgery allows dynamic assessment prior to and following definitive surgical treatment.
  - Arthroscopic surgery demands understanding of the pathoanatomy and correction based on this. Dynamic evaluation difficult
  - The decision for treatment lies with the surgeons assessment of their ability to completely correct the underlying cause of FAI

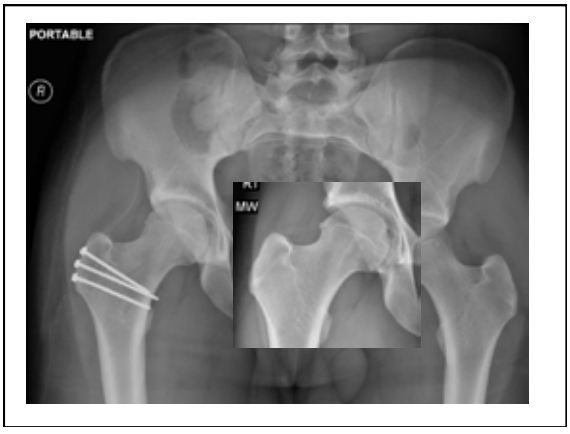
Examples

- 23 y/o club soccer player
- 1 yr Right Groin pain
- Exam with diminished IR
  - anterior impingement, no lateral impingement



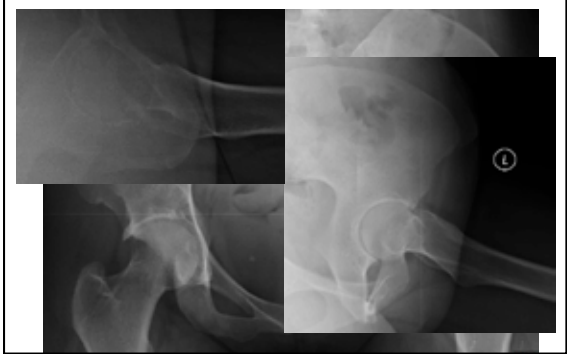


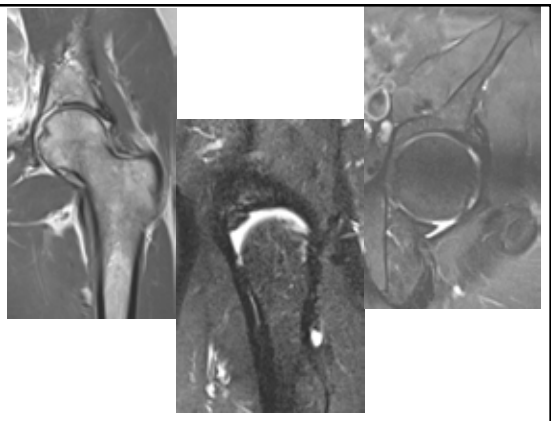


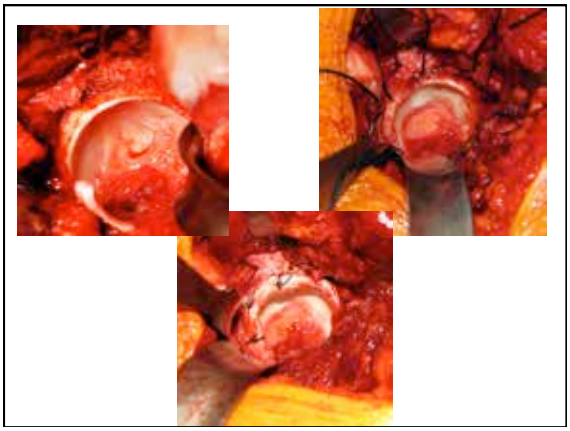


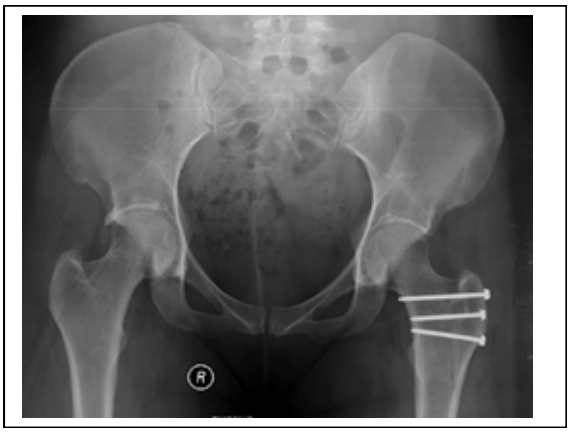
PORTABLE
R
MW

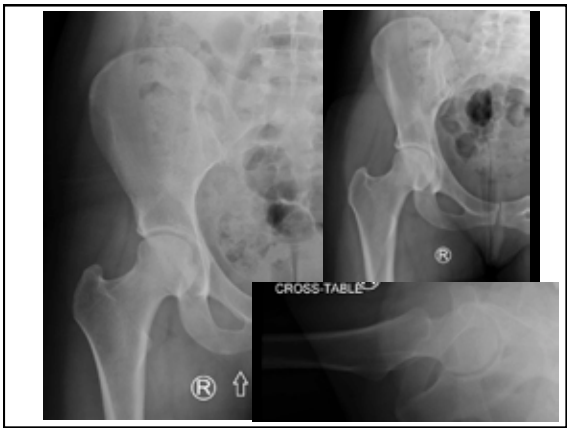
36 y/o with L > R groin pain











CROSS-TABLE

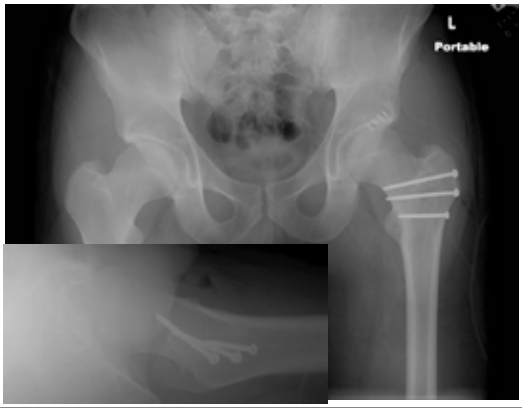
Failed Arthroscopic Treatment



FAI Surgical Indications

- The same for whatever technique is used
- Growing skills of arthroscopists have limited primary open procedures to
  - Cases when additional reconstructive surgery indicated
  - Cartilage lesions with advanced reconstruction

Cautionary note: a large percentage of my open practice is for failed arthroscopy
